## Tank heat transfer systems

### Description:

Tank heat transfer systems are used to transfer large amounts of energy in small domestic hot water tanks. Thus, small and hygienically unproblematic domestic hot water tanks can be used for large amounts of tapped water or for large tap fluctuations. Furthermore, domestic hot water tanks should be of a small size to assure short "dwell periods" of the potable water and to rapidly heat the "fresh" potable water.

As a result of the heat exchanger integrated in the installation and not in the storage tank, a nearly arbitrary assignment of heat exchanger performances (or boiler outputs) to the storage tank size is possible. The heat exchanger performance is fully available during the withdrawal of domestic hot water as well as immediately after a tapping process.

The generously dimensioned heat exchangers result in a large temperature difference. Tank heat transfer systems are therefore optimally suited for the use in combination with district heating and heating value operation.

Using a tank heat transfer module enables a complete and hygienic heating of the storage tank content. Tank heat transfer systems are designed in such a way that the indicated quantity of potable water (see the output capacity tables on page 12 + 14) is heated up to the nominal temperature chosen in one passage through the station - without temperature fluctuations or overheating. This is also the case if the storage tank content cools down as a result of a longer service life or of the operation of circulation systems above the nominal temperature. In this case, only a reheating (with a considerably smaller temperature difference) must be assured.

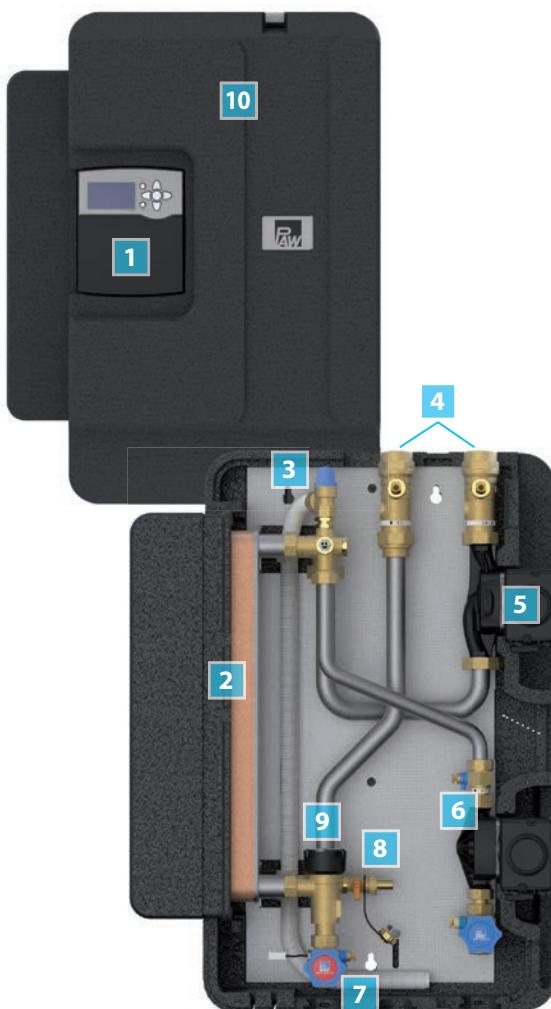

The PAW tank heat transfer module is equipped with a controller which has been developed specifically for this case of operation. The desired nominal temperature is set at the controller. The output of the secondary pump can also be set to reduce the transfer capacity or to adapt f. ex. to smaller boilers. Furthermore, a circulation pump (unregulated as well as controlled by PWM signal) can be connected with the controller. An additional relay can be installed for a targeted stratification. Furthermore, a potential-free relay (f. ex. as boiler demand) and a relay which switches on in parallel with the charging function of the tank heat transfer module are available.

### Functioning:

If the temperature in the domestic hot water tank (secondary tank) falls below the nominal temperature set, the charging cycle is started. If the temperature of the heat source is not sufficient, the potential-free relay is switched on (depending on the system) for the reheating demand. If the temperature available on the primary side is not sufficient, the output of the secondary pump is possibly reduced. Depending on the temperatures and the flow rate of the secondary (potable water) side, the primary pump is controlled in such a way that the adjustable nominal temperature is reached. A relay switching on simultaneously with the primary or secondary pump enables the use of a non-return valve or the switching of a 3-way valve (heating operation / domestic hot water operation).

When using a switch valve it is possible, depending on the primary return temperature of the station, to stratify the return flow rate in the primary storage tank in two different levels. An additional relay with a corresponding PWM outlet allows the connection of a controlled circulation pump. The circulation pump can be activated depending on the temperature and the time. Furthermore, the controller contains a time-dependent disinfection control.

#### **1 Integrated controller FC4.13 with additional functions:**

- fast potable water heating with precise temperatures
- adjustable and limitable transfer capacity
- parallel relay for demand approval
- stratification return on the primary side
- circulation pump operation with weekly timer and / or depending on the temperature
- circulation pump operation for thermal disinfection
- potential-free relay, f. ex. for boiler demand

#### **2 Generously dimensioned high-efficiency plate heat exchanger:**

- with long thermal length for a low return temperature
- made of AISI 316
- Midi: 40 plates
- Maxi: 60 plates

#### **3 Integrated pressure relief valve**

10 bar

#### **4 Ball valves**

with integrated non-return valve

#### **5 High-efficiency pumps Midi / Maxi:**

- with serial number
- ErP and EuP READY
- up to 50% energy saving
- better controllability
- works silently

#### **6 Integrated non-return valve in the circulation line**

- with drain valve

#### **7 Maintenance-free piston valves**

for a quick and save shutoff of the module in case of servicing

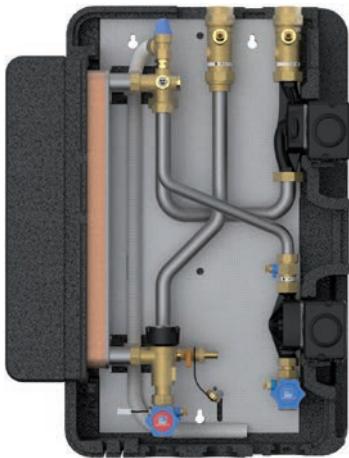

#### **8 Fast temperature sensor**

for optimum control results

#### **9 FlowSonic**

with minimised pressure loss and large measuring range:  
1–130 l/min

#### **10 EnEV compliant design insulation**

**Tank heat transfer module

## Controller FC4.13 for tank heat transfer module

The controller FC4.13 regulates the domestic hot water temperature of the tank heat transfer module via revolution speed control of the primary pump. As an additional function, the controller can carry out the switching of the return diverting valve. Different operation modes are available, they can be adapted individually to the requirements of the system. The tank heat transfer module can be used as preheating station or as storage tank system with and without buffer tank.

The pumps are actuated via a PWM signal. A switch output for switching the return diverting valve is available.

### Additional functions:

**Circulation:** Control via an adjustable time slot or minimum temperature at the sensor S8, switches a pump R3 if necessary (with PWM 3)

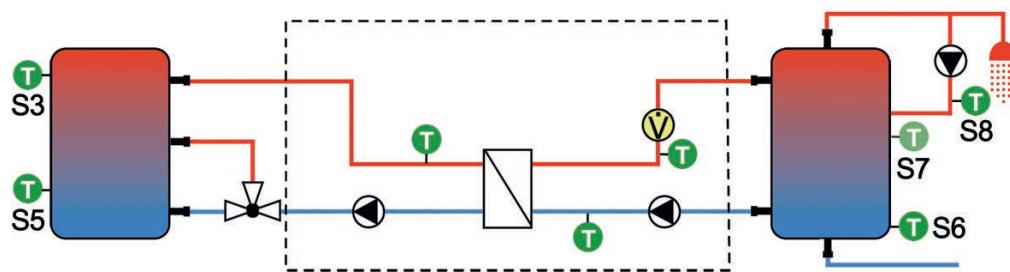

**Thermal disinfection:** Control via an adjustable time slot during which an increased temperature must be reached in the circulation line (sensor S8). The nominal temperature of the boiler is increased during the disinfection period according to the nominal temperature set for the disinfection.

**Parallel relay:** In parallel with the operation of the tank heat transfer module (in parallel with the charging cycle), the relay R1 is switched so that additional consumers can be switched free from tension in standby operation if necessary.

### Function overview controller FC4.13

Display	multiline LC text display, illuminated, with menu navigation (multilingual)
Operation	7 push buttons
Relay outputs	3 x semiconductor relays, 230 V 1 x potential-free relay 4 x PWM signal (0-10 V) for revolution speed control
Inputs	9 (10) x Pt1000 1 x impulse input V40
Flow rate sensors	yes
Heat quantity balancing	yes
Return distribution	yes

### Sketch of the system:

Tank heat transfer module - Basic system with return distribution and circulation

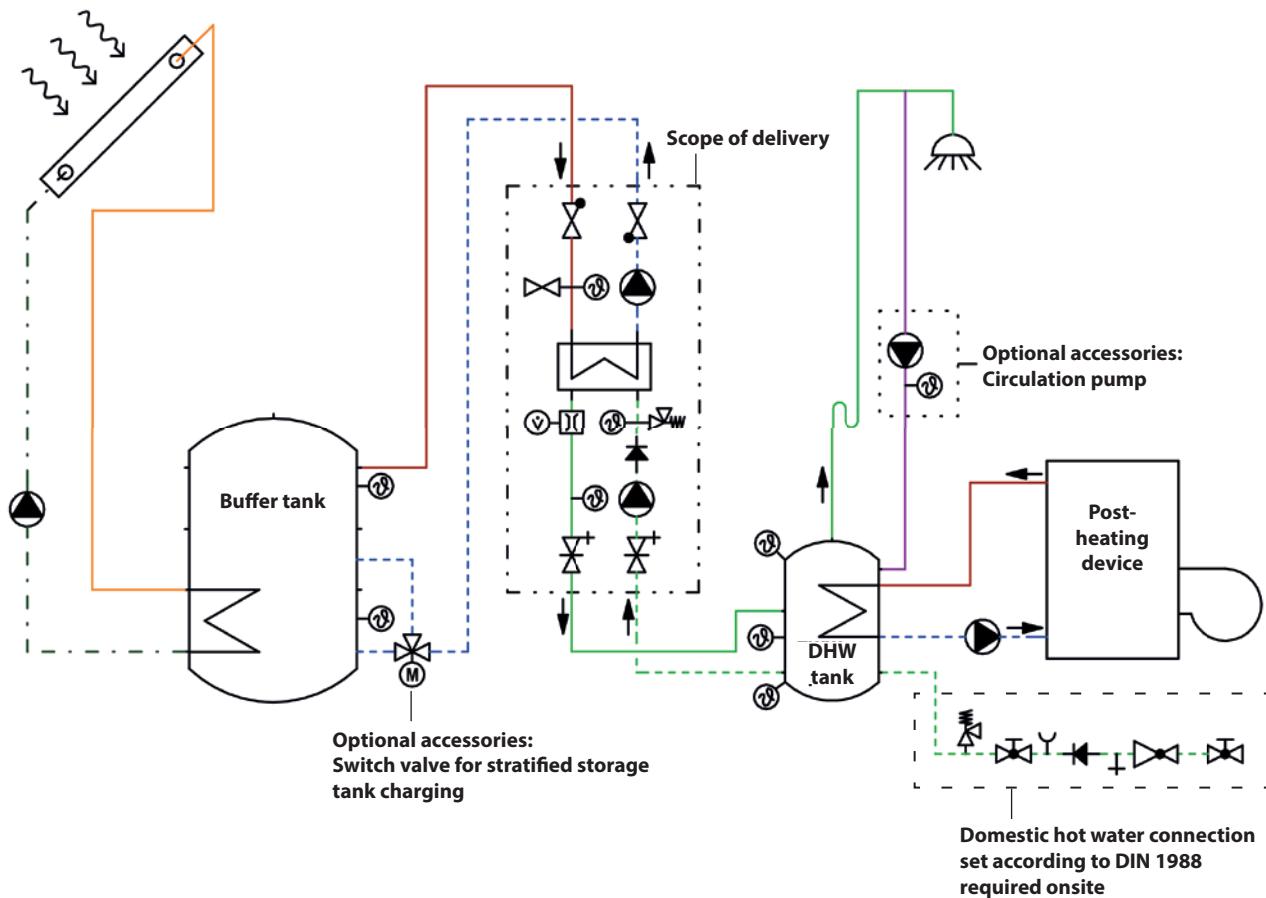

In general, **tank heat transfer modules** have been developed to rapidly prepare large quantities of domestic hot water without the need to store them.

For this purpose, tank heat transfer modules are equipped with a large and high-performance heat exchanger which immediately transfers the output available on the primary side to the potable water on the secondary side without wasting energy or time and with precise temperatures.

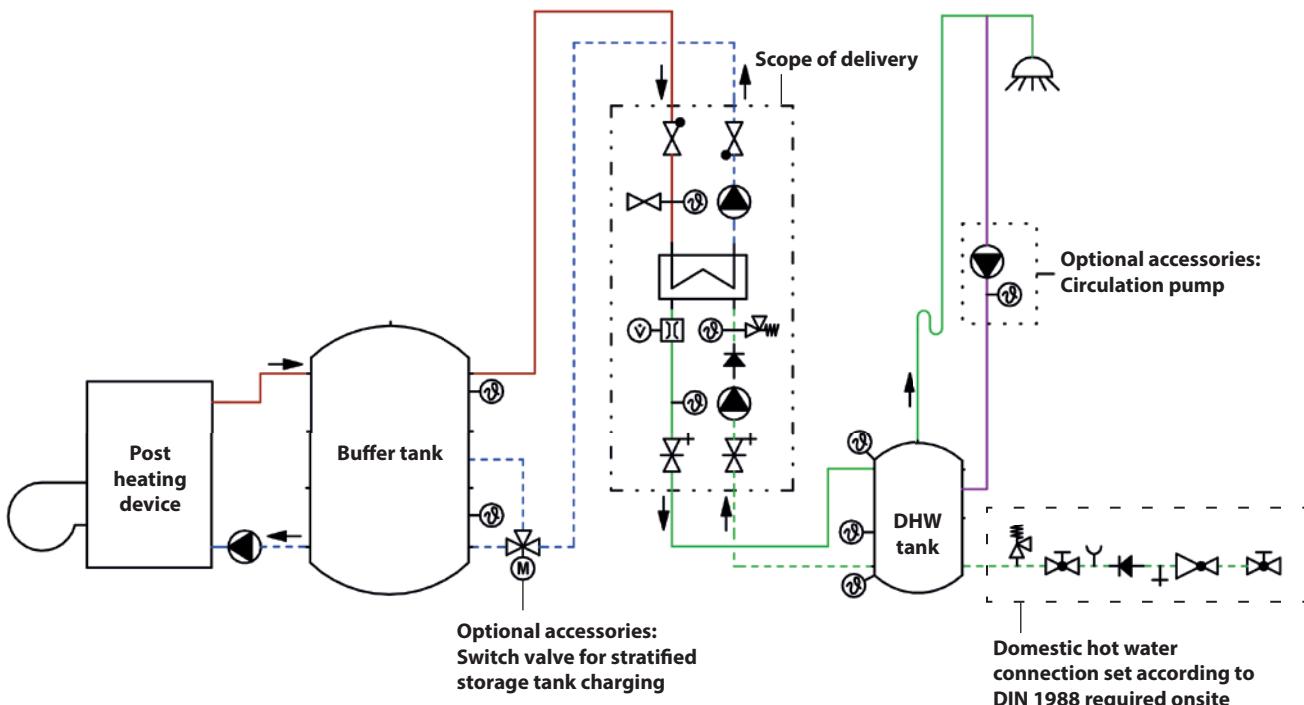

#### Example 1: As preheating station

- All the energy available in the buffer tank is transferred to the domestic hot water storage tank on request (even if the nominal / target temperature is not reached).
- The potential-free relay is controlled by an additional temperature sensor in the domestic hot water storage tank to actuate the post-heating.

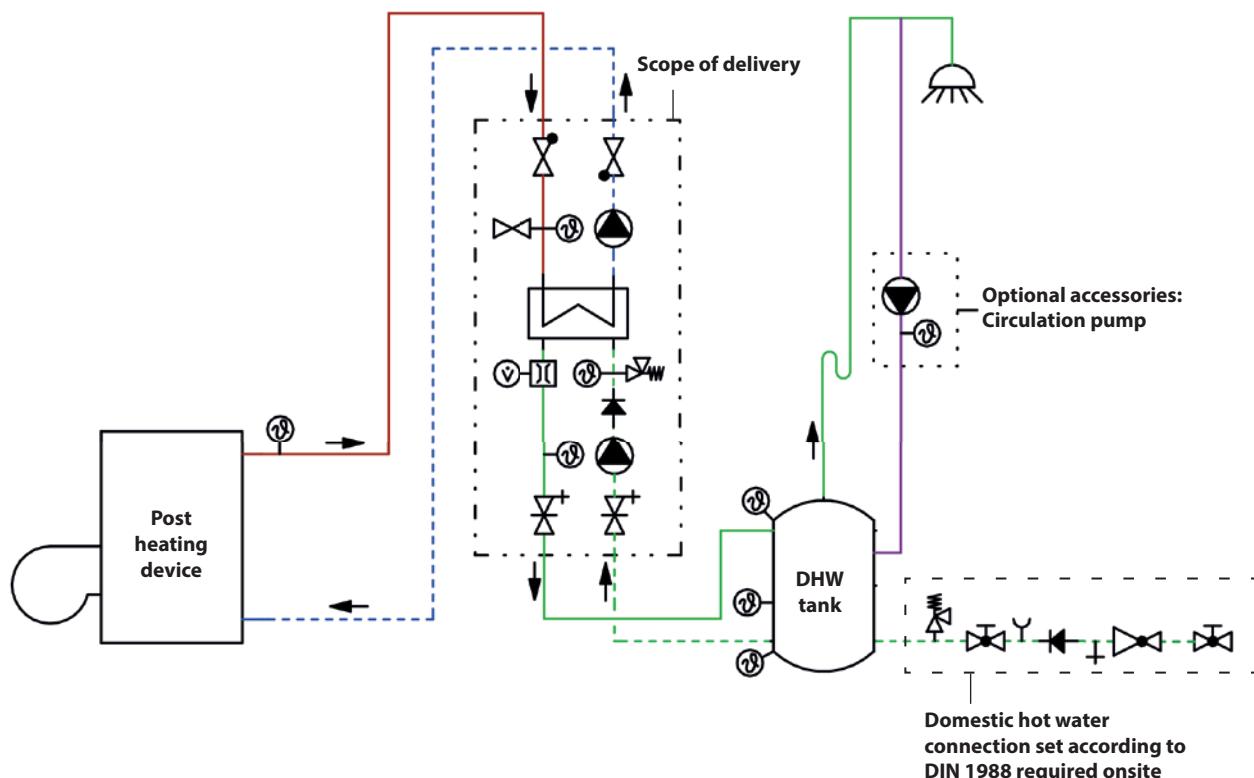

**Example 2: As storage tank module with buffer tank**

- If the required buffer tank temperature is not reached, the post-heating device is activated. The potential-free relay is switched.
- The post-heating demand can occur continuously or on request.

**Example 3: As storage tank module without buffer tank**

- If the nominal temperature set for the potable water is not reached, the post-heating device is activated. The potential-free relay is switched.
- The transfer capacity of the station can be adapted very well to the performance of the post-heating device by limiting the output of the secondary pump. A switching of the post-heating device as well as an insufficient flow temperature are thus avoided.
- An optimum cooling down of the primary return is achieved by using large heat exchangers, the return temperatures are generally of 12–15 °C. Thus, heating value devices achieve their optimum efficiency.

\* The maximum flow rate of the domestic hot water charging pump depends on the length and the type of the components integrated in the piping. A PWM signal of 90% corresponds to the maximum flow rate of the pump. The PWM signal is not increased to more than 90%.

\*\* The outputs indicated in the following table serve only as approximate reference value for the dimensioning of the post-heating. Because of pressure losses and different insulations of the buffer charging circuit, the required outputs can be higher as indicated in order to assure a continuous domestic hot water supply.

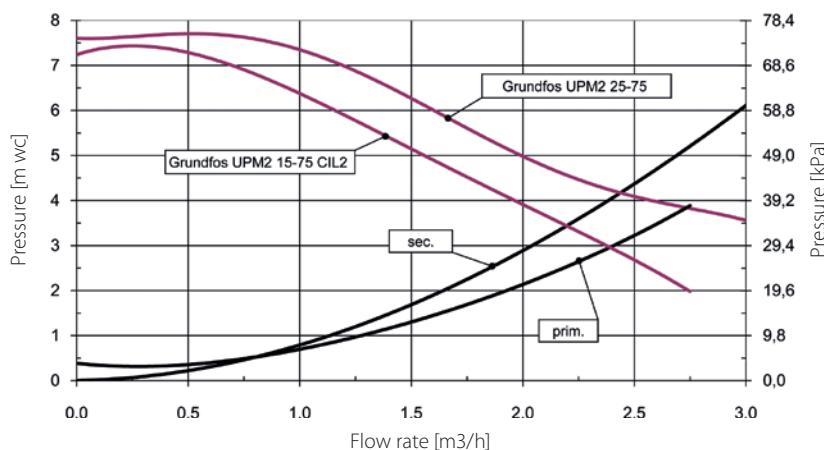

\*\*\* The return temperature is reached at a cold water temperature of 10 °C.

**Example:** 65 °C in the boiler flow (primary) and 50 °C domestic hot water temperature set at the controller (secondary):

- At 65 °C in the boiler flow, at most 44 litres of potable water/minute can be heated up to 50 °C
- This withdrawal corresponds to an output of 122 kW
- The primary return temperature is of 18 °C

\* The maximum flow rate of the domestic hot water charging pump depends on the length and the type of the components integrated in the piping. A PWM signal of 90% corresponds to the maximum flow rate of the pump. The PWM signal is not increased to more than 90%.

\*\* The outputs indicated in the following table serve only as approximate reference value for the dimensioning of the post-heating. Because of pressure losses and different insulations of the buffer charging circuit, the required outputs can be higher as indicated in order to assure a continuous domestic hot water supply.

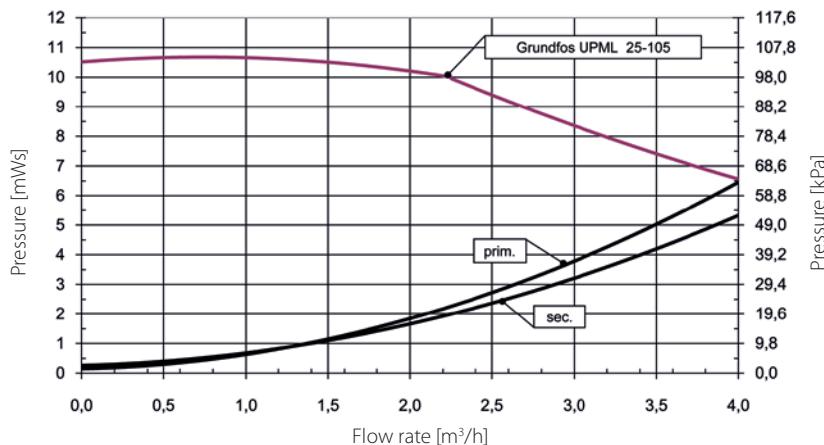

\*\*\* The return temperature is reached at a cold water temperature of 10 °C.

**Example:** 65 °C in the boiler flow (primary) and 50 °C domestic hot water temperature set at the controller (secondary):

- At 65 °C in the boiler flow, at most 64 litres of potable water/minute can be heated up to 50 °C
- This withdrawal corresponds to an output of 178 kW
- The primary return temperature is of 18 °C

### Tank heat transfer module Maxi up to 63 l/min

#### Tank heat transfer module Maxi – DN 25

Item no.

#### Tank heat transfer module Maxi - up to 63 l/min

prim.: Grundfos UPML 25-105, sec.: Grundfos UPML 25-105 N

6436465

Accessories	Item no.
	<b>6404242</b> Return distribution set 1½" internal thread for tank heat transfer module Maxi 3-way valve with actuator, setting time for 90°: 35 sec., Kvs value: 25
	<b>563552</b> Zone valve UV2 with actuator for connecting and disconnecting single storage tanks, DN 25, 1" internal thread, setting time for 90°: 30 sec.
	<b>640422</b> Withdrawal valve flame-treated valves for sterile withdrawal of water. For the subsequent installation inside the tank heat transfer module on each piston valve of the domestic hot water circuit.
	<b>6404136GH7</b> Circulation set - with piston valves, non-return valve and drain valve - with high-efficiency pump Grundfos UPM2 15-75 CIL2, connection 1"
	<b>6404136GH10</b> <b>Zirkulationsset</b> - with piston valves, non-return valve and drain valve - with high-efficiency pump Grundfos UPML 25-105 N, connection 1½"
